Abstract This paper focuses on the problem of the mean square optimal estimation of linear functionals which depend on the unknown values of a multidimensional stationary stochastic sequence. Estimates are based on observations of the sequence with an additive stationary noise sequence. The aim of the paper is to develop methods of finding the optimal estimates of the functionals in the case of missing observations. The problem is investigated in the case of spectral certainty where the spectral densities of the sequences are exactly known. Formulas for calculating the mean-square errors and the spectral characteristics of the optimal linear estimates of functionals are derived under the condition of spectral certainty. The minimax (robust) method of estimation is applied in the case of spectral uncertainty, where spectral densities of the sequences are not known exactly while sets of admissible spectral densities are given. Formulas that determine the least favorable spectral densities and the minimax spectral characteristics of the optimal estimates of functionals are proposed for some special sets of admissible densities.

Keywords Stationary sequence, mean square error, minimax-robust estimate, least favorable spectral density, minimax spectral characteristic

DOI: 10.19139/soic.v7i1.527

1. Introduction

The problem of estimation of the unknown values of stochastic processes is of constant interest in the theory and applications of stochastic processes. The formulation of the estimation problems (interpolation, extrapolation and filtering) for stationary stochastic sequences with known spectral densities and reducing these problems to the corresponding problems of the theory of functions belongs to Kolmogorov\textsuperscript{[17]}. Effective methods of solution of the estimation problems for stationary stochastic sequences and processes were developed by Wiener\textsuperscript{[39]} and Yaglom\textsuperscript{[40, 41]}. Further results are described in the books by Rozanov\textsuperscript{[36]}, Hannan\textsuperscript{[12]}, Box et. al\textsuperscript{[3]}, Brockwell and Davis\textsuperscript{[4]}. The crucial assumption of most of the methods developed for estimating the unobserved values of stochastic processes is that the spectral densities of the involved stochastic processes are exactly known. In practice, however, complete information on the spectral densities is impossible in most cases. In this situation one finds parametric or nonparametric estimates of the unknown spectral densities and then apply one of the traditional estimation methods provided that the selected spectral densities are true. This procedure can result in significant increasing of the value of the error of estimate as Vastola and Poor\textsuperscript{[38]} have demonstrated with the help of some examples. To avoid this effect one can search estimates which are optimal for all densities from a certain given class of admissible spectral densities. These estimates are called minimax since they minimize the
maximum value of the error of estimates. The paper by Grenander [11] was the first one where this approach to extrapolation problem for stationary processes was proposed. Several models of spectral uncertainty and minimax-robust methods of data processing can be found in the survey paper by Kassam and Poor [16]. Franke [7, 8], Franke and Poor [9] investigated the minimax extrapolation and filtering problems for stationary sequences with the help of convex optimization methods. This approach makes it possible to find equations that determine the least favorable spectral densities for some classes of admissible densities. In the papers by Moklyachuk [22, 23] results of investigation of the extrapolation, interpolation and filtering problems for functionals which depend on the unknown values of stationary processes and sequences are described. The problem of estimation of functionals which depend on the unknown values of multivariate stationary stochastic processes is the aim of the papers by Moklyachuk and Masyutka [24, 25]. In the book by Moklyachuk and Golichenko [26] results of investigation of the interpolation, extrapolation and filtering problems for periodically correlated stochastic sequences are proposed. In their papers Luz and Moklyachuk [18, 19] deal with the problems of estimation of functionals which depend on the unknown values of stochastic sequences with stationary increments. Prediction problem for stationary sequences with missing observations is investigated in papers by Bondon [1, 2, 3], Cheng, Miamee and Pourahmadi [5], Cheng and Pourahmadi [6], Kasahara, Pourahmadi and Inoue [15], Pourahmadi, Inoue and Kasahara [33], Pelagatti [32]. In papers by Moklyachuk and Sidei [28, 29] an approach is developed to investigation of the interpolation, extrapolation and filtering problems for stationary stochastic sequences with missing observations.

In this paper we present results of investigation of the problem of the mean-square optimal estimation of the linear functional

\[ A\hat{\xi} = \sum_{j=0}^{\infty} \hat{a}(j)^{\top} \hat{\xi}(j) \]

which depends on the unknown values of a multivariate stationary stochastic sequence \( \{\xi(j), j \in \mathbb{Z}\} \). Estimates are based on the results of investigation of the problem of the mean-square optimal estimation of the linear functional

\[ A\hat{\xi} = \sum_{j=0}^{\infty} \hat{a}(j)^{\top} \hat{\xi}(j) \]

which depends on the unknown values of a multivariate stationary stochastic sequence \( \{\xi(j), j \in \mathbb{Z}\} \). Estimates are based on observations of the sequence with an additive stationary stochastic noise sequence \( \{\xi(j) + \eta(j)\} \) at points \( j \in \mathbb{Z} \setminus S = \{\ldots, -2, -1\} \setminus S, \) where \( S = \bigcup_{l=1}^{s} \{-M_l - N_l, -M_l - N_l + 1, \ldots, -M_l\} \). The problem is investigated in the case of spectral certainty, where the spectral densities of the signal and the noise sequences \( \{\xi(j), j \in \mathbb{Z}\} \) and \( \{\eta(j), j \in \mathbb{Z}\} \) are exactly known, and in the case of spectral uncertainty, where the spectral densities of the sequences are not exactly known while a set of admissible spectral densities is given. We first propose results of investigation of the mean-square optimal linear estimate of the linear functional in the case of spectral certainty. To find the optimal solution of the estimation problem in this case we apply an approach based on the Hilbert space projection method proposed by Kolmogorov [17] and developed in the papers by Moklyachuk [22, 23], and Moklyachuk and Masyutka [24, 25]. We derive formulas for calculation the spectral characteristic and the mean-square error of the optimal estimate of the functional. Next, in the case of spectral uncertainty, where the full information on spectral densities is impossible, while it is known that spectral densities of the sequences belong to some specified classes of admissible densities, the minimax-robust method of estimation is applied. This method gives us a procedure of finding estimates which minimize the maximum values of the mean-square errors of the estimates for all spectral densities from a given class of admissible spectral densities. Formulas that determine the least favorable spectral densities and the minimax-robust spectral characteristics of the optimal estimates of the functional are proposed for some specific classes of admissible spectral densities.

2. Hilbert space projection method of extrapolation of stationary sequences with missing observations

Let \( \xi(j) = \{\xi_k(j)\}_{k=1}^{T}, \) \( j \in \mathbb{Z} \) and \( \eta(j) = \{\eta_k(j)\}_{k=1}^{T}, \) \( j \in \mathbb{Z}, \) be multidimensional stationary stochastic sequences with zero mean values: \( E\xi(j) = 0, \) \( E\eta(j) = 0 \) and correlation functions which admit the spectral decomposition (see Gikhman and Skorokhod [10])

\[ R_{\xi}(n) = E\xi(j + n)(\xi(j))^* = \frac{1}{2\pi} \int_{-\pi}^{\pi} e^{in\lambda} F(\lambda) d\lambda, \quad R_{\eta}(n) = E\eta(j + n)(\eta(j))^* = \frac{1}{2\pi} \int_{-\pi}^{\pi} e^{in\lambda} F_{\eta}(\lambda) d\lambda, \]

\[ R_{\eta\xi}(n) = E\hat{\eta}(j + n)(\xi(j))^* = \frac{1}{2\pi} \int_{-\pi}^{\pi} e^{in\lambda} F_{\eta\xi}(\lambda) d\lambda, \quad R_{\eta}(n) = E\hat{\eta}(j + n)(\eta(j))^* = \frac{1}{2\pi} \int_{-\pi}^{\pi} e^{in\lambda} G(\lambda) d\lambda, \]

where \( F(\lambda) = \{f_{ki}(\lambda)\}_{k,l=1}^{T} \) and \( F_{\eta\xi}(\lambda) = \{f_{kl}^{\eta\xi}(\lambda)\}_{k,l=1}^{T} \) are spectral densities of the stationary sequences such that the minimality condition holds true \( A\vec{\xi} \) is satisfied. This condition ensures that the functional \( \{ \xi \} \) is known, we can use the Hilbert space projection method proposed by Kolmogorov (see selected works of Kolmogorov [17]) to find the estimate \( \hat{A}\vec{\xi} \).

Making use of the spectral decomposition (2) of the sequence \( \vec{\xi}(j) \) we can represent the functional \( A\vec{\xi} \) in the form

\[ A\vec{\xi} = \int_{-\pi}^{\pi} (A(e^{i\lambda}))^\top \xi(\lambda), \quad A(e^{i\lambda}) = \sum_{j=0}^{\infty} \vec{a}(j) e^{ij\lambda}. \]

We will suppose that the coefficients \( \{\vec{a}(j), j = 0, 1, \ldots\} \) which determine the functional \( A\vec{\xi} \) are such that the following condition

\[ \sum_{j=0}^{\infty} \sum_{k=1}^{T} |a_k(j)| < \infty \]

is satisfied. This condition ensures that the functional \( A\vec{\xi} \) has a finite second moment.

Denote by \( \hat{A}\vec{\xi} \) the optimal linear estimate of the functional \( A\vec{\xi} \) from the known observations of the sequence \( \vec{\xi}(j) + \vec{\eta}(j) \) at points \( j \in \mathbb{Z}_- \setminus S \). Since the spectral densities of the stationary sequences \( \vec{\xi}(j) \) and \( \vec{\eta}(j) \) are supposed to be known, we can use the Hilbert space projection method proposed by Kolmogorov (see selected works of Kolmogorov [17]) to find the estimate \( \hat{A}\vec{\xi} \).

Consider values \( \xi_k(j), k = 1, \ldots, T, j \in \mathbb{Z} \), and \( \eta_k(j), k = 1, \ldots, T, j \in \mathbb{Z} \), of the sequences as elements of the Hilbert space \( H = L_2(\Omega, \mathcal{F}, P) \) generated by random variables \( \xi \) with zero mathematical expectations, \( E\xi = 0 \). Under this condition the mean-square error of the optimal estimate of the functional is nonzero (see Rozanov [36]).

The stationary sequences \( \xi(j) \) and \( \eta(j) \) admit the spectral decompositions (see Gikhman and Skorokhod [10], Karhunen [14])

\[ \vec{\xi}(j) = \int_{-\pi}^{\pi} e^{ij\lambda} \xi(\lambda) d\lambda, \quad \vec{\eta}(j) = \int_{-\pi}^{\pi} e^{ij\lambda} \eta(\lambda) d\lambda, \]

where \( \xi(\lambda) \) and \( \eta(\lambda) \) are orthogonal stochastic measures such that the following relations hold true

\[ E\xi(\Delta_1)(\xi(\Delta_2))^* = \frac{1}{2\pi} \int_{\Delta_1 \cap \Delta_2} F(\lambda) d\lambda, \quad E\eta(\Delta_1)(\eta(\Delta_2))^* = \frac{1}{2\pi} \int_{\Delta_1 \cap \Delta_2} F_{\eta}(\lambda) d\lambda, \]

\[ E\xi(\Delta_1)(\xi(\Delta_2)) = \frac{1}{2\pi} \int_{\Delta_1 \cap \Delta_2} F_{\xi}(\lambda) d\lambda, \quad E\eta(\Delta_1)(\eta(\Delta_2)) = \frac{1}{2\pi} \int_{\Delta_1 \cap \Delta_2} G(\lambda) d\lambda. \]
finite variations, $E|\xi|^2 < \infty$, and the inner product $(\xi, \eta) = E(\xi \eta)$. Denote by $H^*(\xi + \eta)$ the closed linear subspace generated by elements $\{\xi_k(j) + \eta_k(j) : j \in \mathbb{Z}_- \setminus S, k = \overline{1, T}\}$ in the Hilbert space $H = L_2(\Omega, F, P)$. Denote by $L_2(F + G)$ the Hilbert space of vector-valued functions $\tilde{a}(\lambda) = \{a_k(\lambda)\}_{k=1}^T$ such that

$$\int_{-\pi}^{\pi} \tilde{a}(\lambda)^\top (F(\lambda) + F_\xi(\lambda) + F_\eta(\lambda) + G(\lambda)) \tilde{a}(\lambda) d\lambda < \infty.$$  

Denote by $L_2^*(F + G)$ the subspace of $L_2(F + G)$ generated by functions of the form $e^{i\lambda k_\delta}, \delta_k = \{\delta_{k_i}\}_{i=1}^T, k = 1, \ldots, T, n \in \mathbb{Z}_- \setminus S$.

The mean-square optimal linear estimate $\hat{A}\xi$ of the functional $A\xi$ from observations of the sequence $\tilde{\xi}(j) + \tilde{\eta}(j)$ is of the form

$$\hat{A}\xi = \int_{-\pi}^{\pi} (h(e^{i\lambda}))^\top (Z\xi(d\lambda) + Z_0(d\lambda)), \quad (4)$$

where $h(e^{i\lambda}) = \{h_k(e^{i\lambda})\}_{k=1}^T \in L_2(F + G)$ is the spectral characteristic of the estimate.

The mean-square error of the estimate $\hat{A}\xi$ is given by the formula

$$\Delta(h; F, G) = E\left|A\xi - \hat{A}\xi\right|^2 =$$

$$= \frac{1}{2\pi} \int_{-\pi}^{\pi} (A(e^{i\lambda}) - h(e^{i\lambda}))^\top F(\lambda)(A(e^{i\lambda}) - h(e^{i\lambda})) d\lambda + \frac{1}{2\pi} \int_{-\pi}^{\pi} (h(e^{i\lambda}))^\top G(\lambda)(h(e^{i\lambda})) d\lambda -$$

$$- \frac{1}{2\pi} \int_{-\pi}^{\pi} (A(e^{i\lambda}) - h(e^{i\lambda}))^\top F_\xi(\lambda) h(e^{i\lambda}) d\lambda - \frac{1}{2\pi} \int_{-\pi}^{\pi} (h(e^{i\lambda}))^\top F_\eta(\lambda)(A(e^{i\lambda}) - h(e^{i\lambda})) d\lambda \quad (5)$$

According to the Hilbert space orthogonal projection method the optimal linear estimate of the functional $A\xi$ is a projection of the element $A\xi$ of the space $H$ on the subspace $H^*(\xi + \eta)$. The projection is determined by the following conditions:

1) $\hat{A}\xi \in H^*(\xi + \eta)$,

2) $A\xi - \hat{A}\xi \perp H^*(\xi + \eta)$.

It follows from the second condition that the spectral characteristic $h(e^{i\lambda}) = \{h_k(e^{i\lambda})\}_{k=1}^T$ of the optimal linear estimate $\hat{A}\xi$ for any $j \in \mathbb{Z}_- \setminus S$ satisfies equations

$$\frac{1}{2\pi} \int_{-\pi}^{\pi} (A(e^{i\lambda}) - h(e^{i\lambda}))^\top F(\lambda) e^{-ij\lambda} d\lambda - \frac{1}{2\pi} \int_{-\pi}^{\pi} (h(e^{i\lambda}))^\top F_\xi(\lambda) e^{-ij\lambda} d\lambda +$$

$$+ \frac{1}{2\pi} \int_{-\pi}^{\pi} (A(e^{i\lambda}) - h(e^{i\lambda}))^\top F_\eta(\lambda) e^{-ij\lambda} d\lambda - \frac{1}{2\pi} \int_{-\pi}^{\pi} (h(e^{i\lambda}))^\top G(\lambda) e^{-ij\lambda} d\lambda = 0.$$

The last relation can be written in the form

$$\frac{1}{2\pi} \int_{-\pi}^{\pi} [(A(e^{i\lambda}))^\top (F(\lambda) + F_\xi(\lambda)) - (h(e^{i\lambda}))^\top (F(\lambda) + F_\xi(\lambda) + F_\eta(\lambda) + G(\lambda))] e^{-ij\lambda} d\lambda = 0, \quad j \in \mathbb{Z}_- \setminus S.$$
Hence the function 

\[ (A(e^{i\lambda}))^T (F(\lambda) + F_{\xi}(\lambda)) - (h(e^{i\lambda}))^T (F(\lambda) + F_{\xi}(\lambda) + F_{\eta}(\lambda) + G(\lambda)) \]

is of the form

\[ (A(e^{i\lambda}))^T (F(\lambda) + F_{\xi}(\lambda)) - (h(e^{i\lambda}))^T (F(\lambda) + F_{\xi}(\lambda) + F_{\eta}(\lambda) + G(\lambda)) = (C(e^{i\lambda}))^T, \]

where \( U = S \cup \{0, 1, \ldots\} \), and \( \bar{c}(j), j \in U \) are the unknown coefficients to be determined.

From the last relation we deduce that the spectral characteristic of the optimal linear estimate \( \hat{A}_\xi \) is of the form

\[ (h(e^{i\lambda}))^T = (A(e^{i\lambda}))^T (F(\lambda) + F_{\xi}(\lambda))(F_{\xi}(\lambda))^{-1} - (C(e^{i\lambda}))^T (F_{\xi}(\lambda))^{-1}, \]

where \( F_{\xi}(\lambda) = F(\lambda) + F_{\xi}(\lambda) + F_{\eta}(\lambda) + G(\lambda) \).

From the first condition, \( \hat{A}_\xi \in H^s(\xi + \eta) \), which determines the optimal estimate of the functional \( A_\xi \), it follows that

\[ \frac{1}{2\pi} \int_{-\pi}^{\pi} h(e^{i\lambda})e^{-ij\lambda} d\lambda = 0, \quad j \in U, \]

namely

\[ \frac{1}{2\pi} \int_{-\pi}^{\pi} ((A(e^{i\lambda}))^T (F(\lambda) + F_{\xi}(\lambda))(F_{\xi}(\lambda))^{-1} - (C(e^{i\lambda}))^T (F_{\xi}(\lambda))^{-1}) e^{-ij\lambda} d\lambda = 0, \quad j \in U. \]

Disclose brackets and write the last equation in the form

\[ \sum_{k=0}^{\infty} (\bar{a}(k))^T \frac{1}{2\pi} \int_{-\pi}^{\pi} (F(\lambda) + F_{\xi}(\lambda))(F_{\xi}(\lambda))^{-1} e^{ikj\lambda} d\lambda - \sum_{l \in U} (\bar{c}(l))^T \frac{1}{2\pi} \int_{-\pi}^{\pi} (F_{\xi}(\lambda))^{-1} e^{ilj\lambda} d\lambda = 0. \]  

Let us introduce the Fourier coefficients of the functions

\[ B(k - j) = \frac{1}{2\pi} \int_{-\pi}^{\pi} (F_{\xi}(\lambda))^{-1} e^{-ikj\lambda} d\lambda; \]

\[ R(k - j) = \frac{1}{2\pi} \int_{-\pi}^{\pi} (F(\lambda) + F_{\xi}(\lambda))(F_{\xi}(\lambda))^{-1} e^{-ikj\lambda} d\lambda; \]

\[ Q(k - j) = \frac{1}{2\pi} \int_{-\pi}^{\pi} F(\lambda)(F_{\xi}(\lambda))^{-1} G(\lambda) - F_{\xi}(\lambda)(F_{\xi}(\lambda))^{-1} F_{\eta}(\lambda) e^{-ikj\lambda} d\lambda. \]

Denote by \( \bar{a}^T = (0, 0, \ldots, 0, \bar{a}^T) \) a vector that has first \( T \cdot |S| = T \cdot \sum_{k=1}^{n} (N_k + 1) \) zero components, and the last component \( \bar{a}^T = (\bar{a}(0)^T, \bar{a}(1)^T \ldots) \) is constructed of coefficients which define the functional \( A_\xi \).

Now we can represent relation (7) in the form

\[ R\bar{a} = B\bar{c}, \]  

where \( \bar{c}(j), j \in U \) are the unknown coefficients to be determined.
where \( \vec{c} \) is the vector constructed of the unknown coefficients \( \vec{c}(k), k \in U \). The linear operator \( B \) in the space \( \ell_2 \) is defined by the matrix

\[
B = \begin{pmatrix}
B_{s,s} & B_{s,s-1} & \cdots & B_{s,1} & B_{s,n} \\
B_{s-1,s} & B_{s-1,s-1} & \cdots & B_{s-1,1} & B_{s-1,n} \\
\vdots & \vdots & \ddots & \vdots & \vdots \\
B_{1,s} & B_{1,s-1} & \cdots & B_{1,1} & B_{1,n} \\
B_{n,s} & B_{n,s-1} & \cdots & B_{n,1} & B_{n,n}
\end{pmatrix},
\]

where elements in the last column and the last row are compound matrices constructed with the help of the block-matrices

\[
B_{l,n}(k, j) = B(k - j), \; l = 1, 2, \ldots, s; \; k = -M_l - N_l, \ldots, -M_l; \; j = 0, 1, 2, \ldots,
\]

\[
B_{n,m}(k, j) = B(k - j), \; m = 1, 2, \ldots, s; \; k = 0, 1, 2, \ldots; \; j = -M_m - N_m, \ldots, -M_m,
\]

\[
B_{a,n}(k, j) = B(k - j), \; k, j = 0, 1, 2, \ldots,
\]

and other elements of matrix \( B \) are compound matrices constructed with the help of the block-matrices

\[
B_{l,m}(j, k) = B(k - j), \; l, m = 1, 2, \ldots, s; \; k = -M_l - N_l, \ldots, -M_l; \; j = -M_m - N_m, \ldots, -M_m.
\]

The linear operator \( R \) in the space \( \ell_2 \) is defined by the corresponding matrix in the same manner. The unknown coefficients \( \vec{c}(k), k \in U \), which are determined by equation (9) can be calculated by the formula

\[
\vec{c}(k) = (B^{-1}R\vec{a})(k),
\]

where \( (B^{-1}R\vec{a})(k) \) is the \( k \)-th component of the vector \( B^{-1}R\vec{a} \). We will suppose that the operator \( B \) is invertible (see paper by Salehi [37] for more details).

Hence the spectral characteristic \( h(e^{i\lambda}) \) of the estimate \( \hat{A}^{\tau} \) can be calculated by the formula

\[
(h(e^{i\lambda}))^\top = (A(e^{i\lambda}))^\top (F(\lambda) + F_\xi(\lambda))(F_\zeta(\lambda))^{-1} - \left( \sum_{k \in T} (B^{-1}R\vec{a})(k)e^{ik\lambda} \right)^\top (F_\zeta(\lambda))^{-1}.
\]

The mean-square error of the estimate \( \hat{A}^{\tau} \) can be calculated by the formula (5) which can be represented in the form

\[
\Delta(h; F, G, F_\xi, F_\eta) = E \left| \hat{A}^{\tau} - \hat{A}^{\tau} \right|^2 =
\]

\[
= \frac{1}{2\pi} \int_{-\pi}^{\pi} (a(\lambda))^\top F(\lambda) \overline{a(\lambda)} d\lambda + \frac{1}{2\pi} \int_{-\pi}^{\pi} (b(\lambda))^\top G(\lambda) \overline{b(\lambda)} d\lambda -
\]

\[
- \frac{1}{2\pi} \int_{-\pi}^{\pi} (a(\lambda))^\top F_\xi(\lambda) \overline{b(\lambda)} d\lambda - \frac{1}{2\pi} \int_{-\pi}^{\pi} (b(\lambda))^\top F_\eta(\lambda) \overline{a(\lambda)} d\lambda =
\]

\[
= \frac{1}{2\pi} \int_{-\pi}^{\pi} (A(e^{i\lambda}))^\top (F(\lambda)G(\lambda) - F_\eta(\lambda)F_\xi(\lambda))(F_\zeta(\lambda))^{-1} \overline{A(e^{i\lambda})} d\lambda + \frac{1}{2\pi} \int_{-\pi}^{\pi} (C(e^{i\lambda}))^\top (F_\zeta(\lambda))^{-1} \overline{C(e^{i\lambda})} d\lambda =
\]

\[
= \langle R\vec{a}, B^{-1}R\vec{a} \rangle + \langle Q\vec{a}, \vec{a} \rangle,
\]

where

\[
(a(\lambda))^\top = (A(e^{i\lambda}))^\top (F_\eta(\lambda) + G(\lambda))(F_\zeta(\lambda))^{-1} + (C(e^{i\lambda}))^\top (F_\zeta(\lambda))^{-1},
\]

\[
(b(\lambda))^\top = (A(e^{i\lambda}))^\top (F(\lambda) + F_\xi(\lambda))(F_\zeta(\lambda))^{-1} - (C(e^{i\lambda}))^\top (F_\zeta(\lambda))^{-1},
\]

and $\langle a, c \rangle = \sum_k a_k \bar{c}_k$ is the inner product in the space $\ell_2$.

The linear operator $Q$ in the space $\ell_2$ is defined by the corresponding matrix in the same manner as operator $B$ is defined.

Thus we obtain the following theorem.

**Theorem 2.1**
Let $\{\xi(j), j \in \mathbb{Z}\}$ and $\{\bar{\eta}(j), j \in \mathbb{Z}\}$ be multidimensional stationary stochastic sequences with the spectral density matrices $F(\lambda), F_{\xi\eta}(\lambda), F_{\xi\xi}(\lambda), G(\lambda)$ and let the minimality condition (1) be satisfied. Suppose that condition (3) is satisfied and the operator $B$ is invertible. The spectral characteristic $h(e^{i\lambda})$ and the mean-square error $\Delta(h; F, G, F_{\xi\eta}, F_{\eta\eta})$ of the optimal linear estimate of the functional $A_{\xi}$ which depends on the unknown values of the sequence $\xi(j)$ based on observations of the sequence $\xi(j) + \bar{\eta}(j)$ at points $j \in \mathbb{Z} \setminus S$ can be calculated by formulas (10), (11).

The corresponding results can be obtained for the uncorrelated sequences $\{\xi(j), j \in \mathbb{Z}\}$ and $\{\bar{\eta}(j), j \in \mathbb{Z}\}$. In this case the spectral densities $F_{\xi\eta}(\lambda) = 0$, $F_{\eta\eta}(\lambda) = 0$ and we get the following corollary.

**Corollary 2.1**
Let $\{\xi(j), j \in \mathbb{Z}\}$ and $\{\bar{\eta}(j), j \in \mathbb{Z}\}$ be uncorrelated multidimensional stationary stochastic sequences with spectral densities $F(\lambda)$ and $G(\lambda)$ which satisfy the minimality condition

$$\int_{-\pi}^{\pi} \text{Tr}(F(\lambda) + G(\lambda))^{-1} d\lambda < \infty. \quad (12)$$

Suppose that condition (3) is satisfied and the operator $B$ is invertible. The spectral characteristic $h(e^{i\lambda})$ and the mean-square error $\Delta(F, G)$ of the optimal linear estimate of the functional $A_{\xi}$ which depends on the unknown values of the sequence $\xi(j)$ based on observations of the sequence $\xi(j) + \bar{\eta}(j)$ at points $j \in \mathbb{Z} \setminus S$ can be calculated by the formulas

$$(h(e^{i\lambda}))^\top = (A(e^{i\lambda}))^\top F(\lambda)(F(\lambda) + G(\lambda))^{-1} - \left(\sum_{k \in U} (B^{-1}R \bar{a})(k)e^{ik\lambda}\right)^\top (F(\lambda) + G(\lambda))^{-1}, \quad (13)$$

$$\Delta(h; F, G; E) = E \| A_{\xi} - \hat{A}_{\xi} \|^2 = \frac{1}{2\pi} \int_{-\pi}^{\pi} (r_G(\lambda))^\top F(\lambda) r_G(\lambda) d\lambda + \frac{1}{2\pi} \int_{-\pi}^{\pi} (r_F(\lambda))^\top G(\lambda) r_F(\lambda) d\lambda =$$

$$= \langle R \bar{a}, B^{-1}R \bar{a} \rangle + \langle Q \bar{a}, \bar{a} \rangle, \quad (14)$$

where

$$(r_F(\lambda))^\top = \left( (A(e^{i\lambda}))^\top F(\lambda) - \left(\sum_{k \in U} (B^{-1}R \bar{a})(k)e^{ik\lambda}\right)^\top \right) (F(\lambda) + G(\lambda))^{-1},$$

$$(r_G(\lambda))^\top = \left( (A(e^{i\lambda}))^\top G(\lambda) + \left(\sum_{k \in U} (B^{-1}R \bar{a})(k)e^{ik\lambda}\right)^\top \right) (F(\lambda) + G(\lambda))^{-1},$$

and $B, R, Q$ are linear operators in the space $\ell_2$ that are determined by compound matrices constructed of the block-matrices $B(k - j), R(k - j), Q(k - j)$ respectively which are defined by the Fourier coefficients of the functions.
\[ B(k - j) = \frac{1}{2\pi} \int_{-\pi}^{\pi} (F(\lambda) + G(\lambda))^{-1} e^{-i(k - j)\lambda} d\lambda; \]
\[ R(k - j) = \frac{1}{2\pi} \int_{-\pi}^{\pi} F(\lambda)(F(\lambda) + G(\lambda))^{-1} e^{-i(k - j)\lambda} d\lambda; \]
\[ Q(k - j) = \frac{1}{2\pi} \int_{-\pi}^{\pi} F(\lambda)(F(\lambda) + G(\lambda))^{-1} e^{-i(k - j)\lambda} d\lambda. \] (15)

Consider the estimation problem in the case where the stationary sequence \( \{\xi(j), j \in \mathbb{Z}\} \) is observed without noise. Since in this case \( G(\lambda) = 0 \), the spectral characteristic of the estimate \( \hat{A}\xi \) is of the form
\[ (h(e^{i\lambda}))^T = (A(e^{i\lambda}))^T - (C(e^{i\lambda}))^T (F(\lambda))^{-1}, \quad C(e^{i\lambda}) = \sum_{j \in U} \tilde{c}(j) e^{ij\lambda}, \] (16)
and the system of equations (9) can be represented in the form
\[ \hat{a} = B\hat{c}, \] (17)
where \( B \) is the linear operator in the space \( \ell_2 \) which is constructed with the help of the Fourier coefficients of the function \( (F(\lambda))^{-1} \) and is of the similar form as operators defined before.

Hence, the unknown coefficients \( \tilde{c}(j), j \in U \), can be calculated by the formula
\[ \tilde{c}(j) = (B^{-1}\hat{a}) (j), \]
where \( (B^{-1}\hat{a}) (j) \) is the \( j \)-th component of the vector \( B^{-1}\hat{a} \), and the spectral characteristic of the estimate \( \hat{A}\xi \) is determined by the formula
\[ (h(e^{i\lambda}))^T = \left( \sum_{j=0}^{\infty} \tilde{a}(j) e^{ij\lambda} \right)^T - \left( \sum_{j \in U} (B^{-1}\hat{a}) (j) e^{ij\lambda} \right)^T (F(\lambda))^{-1}. \] (18)

The mean-square error of the estimate \( \hat{A}\xi \) is determined by the formula
\[ \Delta(h; F) = \langle B^{-1}\hat{a}, \hat{a} \rangle. \] (19)

Let us summarize the obtained result in the form of a corollary.

**Corollary 2.2**
Let \( \{\xi(j), j \in \mathbb{Z}\} \) be a multidimensional stationary stochastic sequence with the spectral density \( F(\lambda) \) which satisfy the minimality condition
\[ \int_{-\pi}^{\pi} \text{Tr} (F(\lambda))^{-1} d\lambda < \infty. \] (20)

Suppose that condition (3) is satisfied and the operator \( B \) is invertible. The spectral characteristic \( h(e^{i\lambda}) \) and the mean-square error \( \Delta(h, F) \) of the optimal linear estimate \( \hat{A}\xi \) of the functional \( A\xi \) from observations of the sequence \( \xi(j) \) at points \( j \in \mathbb{Z} \setminus S \), where \( S = \bigcup_{l=1}^{s} \{-M_l - N_l, \ldots, -M_l\} \), can be calculated by formulas (18), (19).

Let $\xi(j)$ and $\eta(j)$ be uncorrelated stationary sequences. Consider the problem of the mean-square optimal linear extrapolation of the functional

$$A_N \tilde{\xi} = \sum_{j=0}^{N} \tilde{a}(j)\,\tilde{\xi}(j)$$

which depends on unknown values of the sequence $\tilde{\xi}(j)$ from observations of the sequence $\tilde{\xi}(j) + \tilde{\eta}(j)$ at points $j \in \mathbb{Z} \setminus S$, where $S = \bigcup_{l=1}^{s} \{ -M_l - N_l, -M_l - N_l + 1, \ldots, -M_l \}$. In order to find the spectral characteristic $h_N(e^{i\lambda})$ of the estimate

$$\hat{A}_N \xi = \int_{-\pi}^{\pi} (h_N(e^{i\lambda}))^{\top} (Z_{\xi}(d\lambda) + Z_{\eta}(d\lambda))$$

and the mean-square error $\Delta(h_N; F, G)$ of the estimate of the functional $A_N \tilde{\xi}$, we define the vector $\tilde{a}_N = (0, 0, \ldots, 0, \tilde{a}_N)$ which has first $T \cdot |S| = T \cdot \sum_{k=1}^{s} (N_k + 1)$ zero components and the last component is $\tilde{a}_N = (\tilde{a}(0)^{\top}, \tilde{a}(1)^{\top}, \ldots, \tilde{a}(N)^{\top}, 0, 0, \ldots)$.

Consider the linear operator $R_N$ in the space $\ell_2$ which is defined as follows: $R_N(k, j) = R(k, j)$, $j \leq N$, $R_N(k, j) = 0$, $j > N$.

Thus the spectral characteristic of the optimal estimation $\hat{A}_N \xi$ can be calculated by the formula

$$\langle h_N(e^{i\lambda}) \rangle^{\top} = (A_N(e^{i\lambda}))^{\top} F(\lambda)(F(\lambda) + G(\lambda))^{-1} - \left( \sum_{k \in U} (B^{-1} R_N \tilde{a}_N)(k) e^{ik\lambda} \right)^{\top} (F(\lambda) + G(\lambda))^{-1}. \quad (21)$$

The mean-square error of the estimate $\hat{A}_N \tilde{\xi}$ is defined by the formula

$$\Delta(h_N; F, G) = E \left| A_N \tilde{\xi} - \hat{A}_N \xi \right|^{2} = \frac{1}{2\pi} \int_{-\pi}^{\pi} (r_F^{N}(\lambda))^{\top} F(\lambda)r_G(\lambda) d\lambda + \frac{1}{2\pi} \int_{-\pi}^{\pi} (r_G^{N}(\lambda))^{\top} G(\lambda)r_F(\lambda) d\lambda =$$

$$\langle R_N \tilde{a}_N B^{-1} R_N \tilde{a}_N \rangle + \langle Q_N \tilde{a}_N, \tilde{a}_N \rangle, \quad (22)$$

where

$$r_F^{N}(\lambda) = \left( (A_N(e^{i\lambda}))^{\top} F(\lambda) - \left( \sum_{k \in U} (B^{-1} R_N \tilde{a}_N)(k) e^{ik\lambda} \right)^{\top} \right) (F(\lambda) + G(\lambda))^{-1},$$

$$r_G^{N}(\lambda) = \left( (A_N(e^{i\lambda}))^{\top} G(\lambda) + \left( \sum_{k \in U} (B^{-1} R_N \tilde{a}_N)(k) e^{ik\lambda} \right)^{\top} \right) (F(\lambda) + G(\lambda))^{-1},$$

and $Q_N$ is the linear operator in the space $\ell_2$, $Q_N(k, j) = Q(k, j)$, $k, j \leq N$, $Q_N(k, j) = 0$ if $k > N$ or $j > N$.

Note, that linear operators $B, R, Q$ are defined in Corollary 2.1.

**Corollary 2.3**

Let $\{ \xi(j), j \in \mathbb{Z} \}$ and $\{ \eta(j), j \in \mathbb{Z} \}$ be uncorrelated multidimensional stationary stochastic sequences with spectral densities $F(\lambda)$ and $G(\lambda)$ which satisfy the minimality condition (1). Suppose that the operator $B$ is invertible.

The spectral characteristic $h_N(e^{i\lambda})$ and the mean-square error $\Delta(h_N; F, G)$ of the optimal linear estimate of the functional $A_N \tilde{\xi}$ which depends on unknown values of the sequence $\tilde{\xi}(j)$ based on observations of the sequence $\tilde{\xi}(j) + \tilde{\eta}(j)$, $j \in \mathbb{Z} \setminus S$ can be calculated by formulas (21), (22).

In the case where the sequence $\{ \tilde{\xi}(j), j \in \mathbb{Z} \}$ is observed without noise we have the following corollary.
Corollary 2.4
Let \( \{\xi(j), j \in \mathbb{Z}\} \) be a multidimensional stationary stochastic sequence with the spectral density \( F(\lambda) \) which satisfy the minimality condition (20). Suppose that the operator \( B \) is invertible. The spectral characteristic \( h_N(e^{i\lambda}) \) and the mean-square error \( \Delta(h_N, F) \) of the optimal linear estimate \( \hat{A}_N\xi \) of the functional \( A_N\xi \) can be calculated by the formulas (23), (24)

\[
(h_N(e^{i\lambda}))^\top = \left( \sum_{j=0}^N \bar{a}(j)e^{ij\lambda} \right)^\top - \left( \sum_{j \in \mathbb{U}} (B^{-1}\bar{a}_N) (j)e^{ij\lambda} \right)^\top (F(\lambda))^{-1},
\]

\[
\Delta(h_N; F) = \langle (B^{-1}\bar{a}_N, \bar{a}_N) \rangle.
\]

The linear operator \( B \) is defined in Corollary 2.1.

In order to demonstrate the developed techniques we propose the following example.

Example 2.1
Consider the problem of the optimal linear estimation of the functional

\[
A_1\xi = \bar{a}(0)^\top \xi(0) + \bar{a}(1)^\top \xi(1)
\]

which depends on the unknown values of a stationary sequence \( \xi(j) = \{\xi_k(j)\}_{k=1}^2 \) from observations of the sequence \( \xi(j) \) at points \( j \in \mathbb{Z} \setminus S \), where \( S = \{-3, -2\} \), \( \bar{a}(0) = (1, 1)^\top \), \( \bar{a}(1) = (1, 1)^\top \). Let \( \xi_1(n) = \xi(n) \) be a stationary stochastic sequence with the spectral density \( f(\lambda) \), and let \( \xi_2(n) = \xi(n) + \eta(n) \), where \( \eta(n) \) is an uncorrelated with \( \xi(n) \) stationary stochastic sequence with the spectral density \( g(\lambda) \). In this case the matrix of spectral densities is of the form

\[
F(\lambda) = \begin{pmatrix} f(\lambda) & f(\lambda) \\ f(\lambda) & f(\lambda) + g(\lambda) \end{pmatrix},
\]

and the inverse matrix is as follows

\[
(F(\lambda))^{-1} = \begin{pmatrix} \frac{1}{f(\lambda)} + \frac{1}{g(\lambda)} & \frac{-1}{g(\lambda)} \\ \frac{-1}{f(\lambda)} & \frac{1}{g(\lambda)} \end{pmatrix}.
\]

Let

\[
f(\lambda) = \frac{1}{|1 - b_1 e^{i\lambda}|^2}, \quad g(\lambda) = \frac{1}{|1 - b_2 e^{i\lambda}|^2}, \quad b_1, b_2 \in \mathbb{R}.
\]

In this case the inverse matrix is of the form

\[
(F(\lambda))^{-1} = \begin{pmatrix} |1 - b_1 e^{i\lambda}|^2 & |1 - b_2 e^{i\lambda}|^2 \\ -|1 - b_2 e^{i\lambda}|^2 & |1 - b_1 e^{i\lambda}|^2 \end{pmatrix} = B(-1)e^{-i\lambda} + B(0) + B(1)e^{i\lambda},
\]

where

\[
B(0) = \begin{pmatrix} 2 + b_1^2 + b_2^2 & -1 - b_2^2 \\ -1 - b_1^2 & 1 + b_2^2 \end{pmatrix}, \quad B(1) = B(-1) = \begin{pmatrix} -b_1 - b_2 & b_2 \\ b_2 & -b_1 \end{pmatrix},
\]

are the Fourier coefficients of the function \( (F(\lambda))^{-1} \).

According to the Corollary 2.4 the spectral characteristic of the optimal estimate \( \hat{A}_1\xi \) of the functional \( A_1\xi \) is calculated by the formula

\[
(h_1(e^{i\lambda}))^\top = \left( \bar{a}(0) + \bar{a}(1)e^{i\lambda} \right)^\top - \left( \sum_{j \in \mathbb{U}} (B^{-1}\bar{a}_1) (j)e^{ij\lambda} \right)^\top (B(-1)e^{-i\lambda} + B(0) + B(1)e^{i\lambda})^\top,
\]

where vector \( \bar{a}_1^\top = (0, 0, 0, 0, \bar{a}(0)^\top, \bar{a}(1)^\top, 0, 0, \ldots) \).

To find the unknown coefficients \( \vec{c}(j) = (B^{-1} \vec{a})_j, j \in U = S \cup \{0, 1, 2, \ldots\} \), we use equation (17), where \( \vec{c}^T = (c(-3)^T, c(-2)^T, c(0)^T, c(1)^T, c(2)^T, c(3)^T, \ldots) \). The operator \( B \) is defined by the matrix

\[
B = \begin{pmatrix}
B(0) & B(-1) & 0 & 0 & 0 & 0 & 0 & \ldots \\
B(1) & B(0) & B(-1) & 0 & 0 & 0 & 0 & \ldots \\
0 & 0 & B(0) & B(-1) & 0 & 0 & 0 & \ldots \\
0 & 0 & B(1) & B(0) & B(-1) & 0 & 0 & \ldots \\
0 & 0 & 0 & B(1) & B(0) & B(-1) & 0 & \ldots \\
0 & 0 & 0 & 0 & B(1) & B(0) & B(-1) & \ldots \\
\vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \ddots
\end{pmatrix}.
\]

We have to find the inverse matrix \( B^{-1} \) which defines the inverse operator \( B^{-1} \). We first represent the matrix \( B \) in the form

\[
B = \begin{pmatrix}
B_{00} & 0 \\
0 & B_{11}
\end{pmatrix},
\]

where

\[
B_{00} = \begin{pmatrix}
B(0) & B(-1) \\
B(1) & B(0)
\end{pmatrix},
\]

\[
B_{11} = \begin{pmatrix}
B(0) & B(-1) & 0 & 0 & 0 & \ldots \\
B(1) & B(0) & B(-1) & 0 & 0 & \ldots \\
0 & B(0) & B(-1) & 0 & 0 & \ldots \\
0 & 0 & B(1) & B(0) & B(-1) & 0 & \ldots \\
0 & 0 & 0 & B(1) & B(0) & B(-1) & \ldots \\
\vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \ddots
\end{pmatrix}.
\]

Making use of the indicated representation we may conclude that the matrix \( B^{-1} \) can be represented in the form

\[
B^{-1} = \begin{pmatrix}
B_{00}^{-1} & 0 \\
0 & B_{11}^{-1}
\end{pmatrix},
\]

where \( B_{00}^{-1}, B_{11}^{-1} \) are inverse matrices to the matrices \( B_{00}, B_{11} \) respectively. The matrix \( B_{00}^{-1} \) can be found in the form

\[
B_{00}^{-1} = \begin{pmatrix}
\frac{1+b_1^2}{A} & \frac{1+b_2^2}{A} & \frac{b_1}{A} & \frac{b_2}{A} \\
\frac{b_1}{A} & \frac{1+b_1^2}{A} + \frac{1+b_2^2}{B} & \frac{b_1}{A} & \frac{b_2}{B} \\
\frac{b_2}{A} & \frac{b_1}{A} & \frac{1+b_2^2}{A} & \frac{1+b_2^2}{A} + \frac{1}{B} \\
\frac{b_1}{A} & \frac{b_2}{A} & \frac{1+b_2^2}{A} & \frac{1+b_2^2}{A} + \frac{1}{B}
\end{pmatrix},
\]

where \( A = 1 + b_1^2 + b_1^4, B = 1 + b_2^2 + b_2^4 \). In order to find the matrix \( (B_{11})^{-1} \) we use the following method. The matrix \( B_{11} \) is constructed with the help of the Fourier coefficients of the function \( (F(\lambda))^{-1} \)

\[
B_{11}(k, j) = B(k - j), \quad k, j = 0, 1, 2, \ldots.
\]

The density \( (F(\lambda))^{-1} \) admits the factorization

\[
(F(\lambda))^{-1} = \sum_{p = -\infty}^{\infty} B(p) e^{ip\lambda} = \left( \sum_{j = 0}^{\infty} \psi(j) e^{-ij\lambda} \right) \cdot \left( \sum_{j = 0}^{\infty} \psi(j) e^{-ij\lambda} \right)^* =
\]

\[
= \left( \sum_{j = 0}^{\infty} \theta(j) e^{-ij\lambda} \right) \cdot \left( \sum_{j = 0}^{\infty} \theta(j) e^{-ij\lambda} \right)^*.
\]
where
\[
\psi(0) = \begin{pmatrix} 1 & 1 \\ 0 & -1 \end{pmatrix}, \psi(1) = \begin{pmatrix} -b_1 & -b_2 \\ 0 & b_2 \end{pmatrix}, \psi(j) = 0, j > 1, \theta(j) = \begin{pmatrix} b_1^j & b_2^j \\ 0 & -b_2^j \end{pmatrix}, j \geq 0.
\]

Hence \( B(p) = \sum_{k=0}^{\infty} \psi(k)(\psi(k+p))^*, p \geq 0 \), and \( B(-p) = (B(p))^*, p \geq 0 \). Then

\[
B(i - j) = \sum_{l=\max(i,j)}^{\infty} \psi(l - i)\psi(l - j)^*.
\]

Denote by \( \Psi \) and \( \Theta \) linear operators in the space \( \ell_2 \) determined by matrices with elements \( \Psi(i, j) = \psi(j - i) \), \( \Theta(i, j) = \theta(j - i) \), for \( 0 \leq i \leq j \), \( \Psi(i, j) = 0 \), \( \Theta(i, j) = 0 \), for \( 0 \leq j < i \). Then elements of the matrix \( B_{11} \) can be calculated by the formula
\[
B_{11}^{-1}(i, j) = (\Theta^*\Theta)^{-1}(i, j) = \sum_{l=0}^{\min(i,j)} (\theta(i - l)^*\theta(j - l)).
\]

From equation (17) we can find the unknown coefficients \( c(j), j \in U, \)
\[
\begin{align*}
\bar{c}(-3) &= \bar{0}, \\
\bar{c}(-2) &= \bar{0}, \\
\bar{c}(0) &= B_{11}^{-1}(0, 0)\bar{a}(0) + B_{11}^{-1}(0, 1)\bar{a}(1), \\
\bar{c}(1) &= B_{11}^{-1}(1, 0)\bar{a}(0) + B_{11}^{-1}(1, 1)\bar{a}(1), \\
\bar{c}(2) &= B_{11}^{-1}(2, 0)\bar{a}(0) + B_{11}^{-1}(2, 1)\bar{a}(1), \\
\vdots \\
\bar{c}(i) &= B_{11}^{-1}(i, 0)\bar{a}(0) + B_{11}^{-1}(i, 1)\bar{a}(1), \quad i > 2.
\end{align*}
\]

Hence the spectral characteristic of the optimal estimate is calculated by the formula
\[
(h_1(e^{i\lambda}))^\top = (\bar{a}(0) + \bar{a}(1)e^{i\lambda})^\top - (\bar{c}(-3)e^{-i\lambda} + \bar{c}(-2)e^{-2i\lambda} + \bar{c}(0) + \bar{c}(1)e^{i\lambda} + \bar{c}(2)e^{2i\lambda} + \sum_{j>2} \bar{c}(j)e^{j\lambda}(B(-1)e^{-i\lambda} + B(0) + B(1)e^{i\lambda}) = -\bar{c}(0)^\top B(-1)e^{-i\lambda} - \bar{c}(1)^\top B(1)e^{i\lambda} - \bar{c}(2)^\top B(0)e^{2i\lambda} - \bar{c}(2)^\top B(1)e^{i\lambda} - \bar{c}(2)^\top B(1)e^{2i\lambda} - \sum_{j>2} \bar{c}(j)^\top e^{j\lambda}(B(-1)e^{-i\lambda} + B(0) + B(1)e^{i\lambda}).
\]

Since coefficients \( \bar{c}(j - 1)^\top B(1) + \bar{c}(j)^\top B(0) + \bar{c}(j + 1)^\top B(-1) \) for \( j \geq 2 \) are zero, the spectral characteristic of the estimate \( \hat{A}_1 \hat{\xi} \) is of the form
\[
(h_1(e^{i\lambda}))^\top = -\bar{c}(0)^\top B(-1)e^{-i\lambda} = (b_2 + b_2^2 - 2(b_1 + b_2), -b_2 - b_2^2) e^{-i\lambda}.
\]

The mean-square error of the estimate of the functional \( A_1 \hat{\xi} \) is calculated by the formula
\[
\Delta(h_1; F) = \langle B^{-1}\bar{\xi}_1, \bar{\xi}_1 \rangle = 10 + 8b_1 + 4b_1^2 + 2b_2 + b_2^2.
\]

3. Minimax approach to extrapolation problem for stationary sequences with missing observations

Theorem 2.1 and its Corollaries 2.1 – 2.4 can be applied for finding solutions of the extrapolation problem for multidimensional stationary sequences with missing observations only in the case of spectral certainty, where
spectral densities $F(\lambda), F_{\xi_\eta}(\lambda), F_{\eta_\xi}(\lambda), G(\lambda)$ are exactly known. If the complete information about spectral densities is impossible while a class of admissible spectral density matrices $D$ is given, the minimax(robust) method of extrapolation is reasonable. It consists in finding an estimate which minimizes the value of the mean-square error for all spectral density matrices from the given class of densities. For description of the minimax method we introduce the following definitions (see Moklyachuk [22, 23], and Moklyachuk and Masytka [25 - 27]).

**Definition 3.1**
For a given class of spectral density matrices $D$ the spectral densities $(F^0(\lambda), F^0_{\xi_\eta}(\lambda), F^0_{\eta_\xi}(\lambda), G^0(\lambda)) \in D$ are called the least favorable in the class $D$ for the optimal linear extrapolation of the functional $A_{\xi}$ if the following relation holds true

$$\Delta \left( h \left( F^0, F^0_{\xi_\eta}, F^0_{\eta_\xi}, G^0 \right) ; F^0, F^0_{\xi_\eta}, F^0_{\eta_\xi}, G^0 \right) = \max_{(F,F,F,F)\in D} \Delta \left( h \left( F, F_{\xi_\eta}, F_{\eta_\xi}, G \right) ; F, F_{\xi_\eta}, F_{\eta_\xi}, G \right).$$

**Definition 3.2**
For a given class of spectral density matrices $D$ the spectral characteristic $h^0(e^{i\lambda})$ of the optimal linear estimate of the functional $A_{\xi}$ is called minimax-robust if there are satisfied conditions

$$h^0(e^{i\lambda}) \in H_D = \bigcap_{F,F_{\xi_\eta},F_{\eta_\xi},G\in D} L_2^s(F + G),$$

$$\min_{h \in H_D} \max_{(F,F_{\xi_\eta},F_{\eta_\xi},G)\in D} \Delta \left( h ; F, F_{\xi_\eta}, F_{\eta_\xi}, G \right) = \max_{(F,F_{\xi_\eta},F_{\eta_\xi},G)\in D} \Delta \left( h^0 ; F, F_{\xi_\eta}, F_{\eta_\xi}, G \right).$$

From the introduced definitions and formulas derived above we can obtain the following statement.

**Lemma 3.1**
Spectral densities $(F^0(\lambda), F^0_{\xi_\eta}(\lambda), F^0_{\eta_\xi}(\lambda), G^0(\lambda)) \in D$, satisfying the minimality condition (1), are the least favorable in the class $D$ for the optimal linear extrapolation of the functional $A_{\xi}$ if the Fourier coefficients (8) of the functions

$$(F^0_{\xi}(\lambda))^{-1}, \quad (F^0(\lambda) + F^0_{\xi}(\lambda))(F^0_{\xi}(\lambda))^{-1}, \quad F^0(\lambda)(F^0_{\xi}(\lambda))^{-1}G^0(\lambda) - F^0_{\xi_\eta}(\lambda)(F^0_{\xi}(\lambda))^{-1}F^0_{\eta_\xi}(\lambda)$$

define operators $B^0, R^0, Q^0$ which determine a solution of the constrained optimization problem

$$\max_{(F,F_{\xi_\eta},F_{\eta_\xi},G)\in D} \left( \langle [R\vec{a}, B^{-1}R\vec{a}] + (Q\vec{a}, \vec{a}) \rangle = \langle R^0\vec{a}, (B^0)^{-1}R^0\vec{a} \rangle + \langle Q^0\vec{a}, \vec{a} \rangle \right).$$

(25)

The minimax spectral characteristic $h^0(e^{i\lambda}) = h(F^0, F^0_{\xi_\eta}, F^0_{\eta_\xi}, G^0)$ is calculated by the formula (10) if $h(F^0, F^0_{\xi_\eta}, F^0_{\eta_\xi}, G^0) \in H_D$.

In the case of uncorrelated stationary sequences the corresponding definitions and lemmas are as follows.

**Definition 3.3**
For a given class of spectral densities $D = D_F \times D_G$ the spectral densities $F^0(\lambda) \in D_F, G^0(\lambda) \in D_G$ are called the least favorable in the class $D$ for the optimal linear extrapolation of the functional $A_{\xi}$ based on observations of the uncorrelated sequences if the following relation holds true

$$\Delta \left( F^0, G^0 \right) = \Delta \left( h \left( F^0, G^0 \right) ; F^0, G^0 \right) = \max_{(F,G)\in D_F \times D_G} \Delta \left( h \left( F, G \right) ; F, G \right).$$

**Definition 3.4**
For a given class of spectral densities $D = D_F \times D_G$ the spectral characteristic $h^0(e^{i\lambda})$ of the optimal linear estimate of the functional $A_{\xi}$ based on observations of the uncorrelated sequences is called minimax-robust if there are satisfied conditions

$$h^0(e^{i\lambda}) \in H_D = \bigcap_{(F,G)\in D_F \times D_G} L_2^s(F + G),$$

$$\min_{h \in H_D} \max_{(F,G)\in D_F \times D_G} \Delta \left( h ; F, G \right) = \max_{(F,G)\in D} \Delta \left( h^0 ; F, G \right).$$
Lemma 3.2
Spectral densities $F^0(\lambda) \in D_F$, $G^0(\lambda) \in D_G$ satisfying the minimality condition (12) are the least favorable in the class $D = D_F \times D_G$ for the optimal linear extrapolation of the functional $A^0$ based on observations of the uncorrelated sequences if the Fourier coefficients (15) of functions

$$(F^0(\lambda) + G^0(\lambda))^{-1}, \quad F^0(\lambda)(F^0(\lambda) + G^0(\lambda))^{-1}, \quad F^0(\lambda)(F^0(\lambda) + G^0(\lambda))^{-1}G^0(\lambda)$$

define operators $B^0, R^0, Q^0$ which determine a solution of the constrained optimization problem

$$\max_{(F,G) \in D_F \times D_G} \langle (R^0\bar{a}, B^{-1}R\bar{a}) + (Q\bar{a}, \bar{a}) \rangle = \langle R^0\bar{a}, (B^0)^{-1}R^0\bar{a} \rangle + \langle Q^0\bar{a}, \bar{a} \rangle. \quad (26)$$

The minimax spectral characteristic $h^0 = h(F^0, G^0)$ is calculated by the formula (13) if $h(F^0, G^0) \in H_D$.

In the case of observations of the sequence without noise we obtain the following corollary.

Corollary 3.1
Let the spectral density $F^0(\lambda) \in D_F$ be such that the function $(F^0(\lambda))^{-1}$ satisfies the minimality condition. The spectral density $F^0(\lambda) \in D_F$ is the least favorable in the class $D_F$ for the optimal linear extrapolation of the functional $A^0$ if the Fourier coefficients of the function $(F^0(\lambda))^{-1}$ define the operator $B^0$ which determines a solution of the optimization problem

$$\max_{F \in D_F} \langle B^{-1}\bar{a}, \bar{a} \rangle = \langle (B^0)^{-1}\bar{a}, \bar{a} \rangle. \quad (27)$$

The minimax spectral characteristic $h^0 = h(F^0)$ is calculated by the formula (18) if $h(F^0) \in H_D$.

The least favorable spectral densities $F^0(\lambda), G^0(\lambda)$ and the minimax spectral characteristic $h^0 = h(F^0, G^0)$ form a saddle point of the function $\Delta(h; F, G)$ on the set $H_D \times D$. The saddle point inequalities

$$\Delta(h; F^0, G^0) \geq \Delta(h^0; F^0, G^0) \geq \Delta(h^0; F, G)$$

$$\forall h \in H_D, \forall F \in D_F, \forall G \in D_G$$

hold true if $h^0 = h(F^0, G^0)$ and $h(F^0, G^0) \in H_D$, where $(F^0, G^0)$ is a solution of the constrained optimization problem

$$\sup_{(F,G) \in D_F \times D_G} \Delta(h(F^0, G^0); F, G) = \Delta(h(F^0, G^0); F^0, G^0), \quad (28)$$

$$\Delta(h(F^0, G^0); F, G) = \frac{1}{2\pi} \int_{-\pi}^{\pi} (r^0_{\lambda}(\lambda))^T F(\lambda)\frac{r^0_{\lambda}(\lambda)}{F(\lambda)}d\lambda + \frac{1}{2\pi} \int_{-\pi}^{\pi} (r^0_{\lambda}(\lambda))^T G(\lambda)\frac{r^0_{\lambda}(\lambda)}{G(\lambda)}d\lambda,$$

$$(r^0_{\lambda}(\lambda))^T = \left((Ae^{i\lambda})^T F^0(\lambda) - \sum_{k \in U} ((B^0)^{-1}R^0\bar{a})(k)e^{ik\lambda}) \right)^T (F^0(\lambda) + G^0(\lambda))^{-1},$$

$$(r^0_{\lambda}(\lambda))^T = \left((Ae^{i\lambda})^T G^0(\lambda) + \sum_{k \in U} ((B^0)^{-1}R^0\bar{a})(k)e^{ik\lambda}) \right)^T (F^0(\lambda) + G^0(\lambda))^{-1}.$$

The constrained optimization problem (28) is equivalent to the unconstrained optimization problem (see Pshenichnyj [34]):

$$\Delta_D(F, G) = -\Delta(h(F^0, G^0); F, G) + \delta((F, G) | D_F \times D_G) \rightarrow \inf,$$

where $\delta((F, G) | D_F \times D_G)$ is the indicator function of the set $D = D_F \times D_G$.

A solution of the problem (29) is determined by the condition $0 \in \partial \Delta_D(F^0, G^0)$, where $\partial \Delta_D(F^0, G^0)$ is the subdifferential of the convex functional $\Delta_D(F, G)$ at point $(F^0, G^0)$. This condition is the necessary and
sufficient condition under which the pair \((F^0, G^0)\) belongs to the set of minimums of the convex functional 
\[ \Delta\left(h(F^0, G^0); F, G\right). \] This condition makes it possible to find the least favourable spectral densities in some special classes of spectral densities \(D\) (see books by Ioffe and Tihomirov [13], Pshenichnyj [34], Rockafellar [35]).

Note, that the form of the functional \(\Delta\left(h^0; F, G\right)\) is convenient for application the Lagrange method of indefinite multipliers for finding solution to the problem (29). Making use the method of Lagrange multipliers and the form of subdifferentials of the indicator functions we describe relations that determine the least favourable spectral densities in some special classes of spectral densities (see books by Moklyachuk [21, 22], Moklyachuk and Masyutka [27] for additional details).

4. Least favorable spectral densities in the class \(D = D_0 \times D^U_v\)

Consider the problem of minimax extrapolation of the functional \(A\) based on observations of the uncorrelated sequences in the case where the spectral density matrices of the observed sequences are not exactly known while the admissible spectral density matrices are from the class \(D = D_0 \times D^U_v\), where

\[
D_0 = \left\{ F(\lambda) \left| \frac{1}{2\pi} \int_{-\pi}^{\pi} \text{Tr} F(\lambda) d\lambda = p \right. \right\},
\]

\[
D^U = \left\{ G(\lambda) \left| \text{Tr} G(\lambda) \leq \text{Tr} U(\lambda), \frac{1}{2\pi} \int_{-\pi}^{\pi} \text{Tr} G(\lambda) d\lambda = q \right. \right\},
\]

\[
D^U_0 = \left\{ F(\lambda) \left| \frac{1}{2\pi} \int_{-\pi}^{\pi} f_{kk}(\lambda) d\lambda = p_k, k = 1, T \right. \right\},
\]

\[
D^U_{U} = \left\{ G(\lambda) \left| v_{kk}(\lambda) \leq g_{kk}(\lambda) \leq u_{kk}(\lambda), \frac{1}{2\pi} \int_{-\pi}^{\pi} g_{kk}(\lambda) d\lambda = q_k, k = 1, T \right. \right\},
\]

\[
D^U_0 = \left\{ F(\lambda) \left| \frac{1}{2\pi} \int_{-\pi}^{\pi} \langle B_1, F(\lambda) \rangle d\lambda = p \right. \right\},
\]

\[
D^U_0 = \left\{ G(\lambda) \left| \langle B_2, V(\lambda) \rangle \leq \langle B_2, G(\lambda) \rangle \leq \langle B_2, U(\lambda) \rangle, \frac{1}{2\pi} \int_{-\pi}^{\pi} \langle B_2, G(\lambda) \rangle d\lambda = q \right. \right\},
\]

\[
D^U_4 = \left\{ F(\lambda) \left| \frac{1}{2\pi} \int_{-\pi}^{\pi} F(\lambda) d\lambda = P \right. \right\},
\]

\[
D^U_4 = \left\{ G(\lambda) \left| \langle V(\lambda) \rangle \geq G(\lambda) \geq U(\lambda), \frac{1}{2\pi} \int_{-\pi}^{\pi} G(\lambda) d\lambda = Q \right. \right\}.
\]

Here spectral densities \(V(\lambda), U(\lambda)\) are known and fixed, \(p, q, p_k, q_k,k = 1, T\) are fixed numbers, \(P, Q, B_1, B_2\) are fixed positive definite Hermitian matrices.

From the condition \(0 \in \partial \Delta_D(F^0, G^0)\) we find the following equations which determine the least favourable spectral densities for these sets of admissible spectral densities.

For the first pair \(D^U_0 \times D^U_1\) we have equations

\[
(r^0_G(\lambda))^\text{T}(r^0_G(\lambda)) = \alpha^2(F^0(\lambda) + G^0(\lambda))^2,
\]

\[
(r^0_F(\lambda))^\text{T}(r^0_F(\lambda)) = (\beta^2 + \gamma_1(\lambda) + \gamma_2(\lambda))(F^0(\lambda) + G^0(\lambda))^2,
\]

where \(\alpha^2, \beta^2\) are Lagrange multipliers, \(\gamma_1(\lambda) \leq 0\) and \(\gamma_2(\lambda) = 0\) if \(\text{Tr} G^0(\lambda) \geq \text{Tr} V(\lambda), \gamma_2(\lambda) \geq 0\) and \(\gamma_2(\lambda) = 0\) if \(\text{Tr} G^0(\lambda) < \text{Tr} U(\lambda)\).

For the second pair \(D^U_0 \times D^U_2\) we have equations

\[
(r^0_G(\lambda))^\text{T}(r^0_G(\lambda)) = (F^0(\lambda) + G^0(\lambda)) \left\{ \alpha^2 \delta_{kl} \right\}_{k,l=1}^T(F^0(\lambda) + G^0(\lambda)),
\]

where $\alpha_k^2, \beta_k^2$ are Lagrange multipliers, $\delta_{kl}$ are Kronecker symbols, $\gamma_{1k}(\lambda) \leq 0$ and $\gamma_{1k}(\lambda) = 0$ if $g_{kk}^0(\lambda) > v_{kk}(\lambda)$, $\gamma_{2k}(\lambda) \geq 0$ and $\gamma_{2k}(\lambda) = 0$ if $g_{kk}^0(\lambda) < u_{kk}(\lambda)$.

For the third pair $D_3^0 \times D_V^3$ we have equations
\begin{equation}
(r_0^0(\lambda))^* (r_G^0(\lambda))^T = \alpha^2 (F^0(\lambda) + G^0(\lambda)) B_1^T (F^0(\lambda) + G^0(\lambda)),
\end{equation}
\begin{equation}
(r_0^0(\lambda))^* (r_G^0(\lambda))^T = (\beta^2 + \gamma_1(\lambda) + \gamma_2(\lambda))(F^0(\lambda) + G^0(\lambda)) B_2^T (F^0(\lambda) + G^0(\lambda)),
\end{equation}
where $\alpha^2, \beta^2$ are Lagrange multipliers, $\gamma_1(\lambda) \leq 0$ and $\gamma_1(\lambda) = 0$ if $\langle B_2, G^0(\lambda) \rangle > \langle B_2, V(\lambda) \rangle$, $\gamma_2(\lambda) \geq 0$ and $\gamma_2(\lambda) = 0$ if $\langle B_2, G^0(\lambda) \rangle < \langle B_2, U(\lambda) \rangle$.

For the fourth pair $D_4^0 \times D_V^4$ we have equations
\begin{equation}
(r_0^0(\lambda))^* (r_G^0(\lambda))^T = (F^0(\lambda) + G^0(\lambda)) \tilde{\alpha} \cdot \tilde{\alpha}^* (F^0(\lambda) + G^0(\lambda)),
\end{equation}
\begin{equation}
(r_0^0(\lambda))^* (r_G^0(\lambda))^T = (F^0(\lambda) + G^0(\lambda))(\tilde{\beta} \cdot \tilde{\beta}^* + \Gamma_0(\lambda) + \Gamma_2(\lambda))(F^0(\lambda) + G^0(\lambda))
\end{equation}
where $\tilde{\alpha}, \tilde{\beta}$ are Lagrange multipliers, $\Gamma_0(\lambda) \leq 0$ and $\Gamma_0(\lambda) = 0$ if $G^0(\lambda) > V(\lambda)$, $\Gamma_2(\lambda) \geq 0$ and $\Gamma_2(\lambda) = 0$ if $G^0(\lambda) < U(\lambda)$.

The following theorem and corollaries hold true.

**Theorem 4.1**
Let the minimality condition (12) hold true. The least favorable spectral densities $F^0(\lambda), G^0(\lambda)$ in the classes $D_0 \times D_V^k$ for the optimal linear extrapolation of the functional $A^0_\xi$ are determined by relations (30), (31) for the first pair $D_0^1 \times D_V^1$ of sets of admissible spectral densities; (32), (33) for the second pair $D_0^2 \times D_V^2$ of sets of admissible spectral densities; (34), (35) for the third pair $D_0^3 \times D_V^3$ of sets of admissible spectral densities; (36), (37) for the fourth pair $D_0^4 \times D_V^4$ of sets of admissible spectral densities; constrained optimization problem (26) and restrictions on densities from the corresponding classes $D_0 \times D_V^k$. The minimax-robust spectral characteristic of the optimal estimate of the functional $A^0_\xi$ is determined by the formula (13).

**Corollary 4.1**
Let the minimality condition (20) hold true. The least favorable spectral densities $F^0(\lambda)$ in the classes $D_0^k, k = 1, 2, 3, 4$, for the optimal linear extrapolation of the functional $A^0_\xi$ from observations of the sequence $\xi(j)$ at points $j \in \mathbb{Z}_- \setminus S$, where $S = \bigcup_{l=1}^{p} \{ -M_l - N_l, \ldots, -M_l \}$, are determined by the following equations, respectively,
\begin{equation}
((C^0(\lambda))^T)^* \cdot (C^0(\lambda))^T = \alpha^2 (F^0(\lambda))^2,
\end{equation}
\begin{equation}
((C^0(\lambda))^T)^* \cdot (C^0(\lambda))^T = (\alpha^2 \delta_{kl})_{k,l=1}^T F^0(\lambda),
\end{equation}
\begin{equation}
((C^0(\lambda))^T)^* \cdot (C^0(\lambda))^T = \alpha^2 F^0(\lambda) B_1^T F^0(\lambda),
\end{equation}
\begin{equation}
((C^0(\lambda))^T)^* \cdot (C^0(\lambda))^T = F^0(\lambda) \tilde{\alpha} \cdot \tilde{\alpha}^* F^0(\lambda),
\end{equation}
constrained optimization problem (27) and restrictions on densities from the corresponding classes $D_0^k$, $k = 1, 2, 3, 4$. The minimax spectral characteristic of the optimal estimate of the functional $A^0_\xi$ is determined by the formula (18).

**Corollary 4.2**
Let the minimality condition (20) hold true. The least favorable spectral densities $F^0(\lambda)$ in the classes $D_V^k, k = 1, 2, 3, 4$, for the optimal linear extrapolation of the functional $A^0_\xi$ from observations of the sequence $\xi(j)$ at points $j \in \mathbb{Z}_- \setminus S$, where $S = \bigcup_{l=1}^{p} \{ -M_l - N_l, \ldots, -M_l \}$, are determined by the following equations, respectively,
\begin{equation}
((C^0(\lambda))^T)^* \cdot (C^0(\lambda))^T = (\beta^2 + \gamma_1(\lambda) + \gamma_2(\lambda))(F^0(\lambda))^2,
\end{equation}
\begin{equation}
((C^0(\lambda))^T)^* \cdot (C^0(\lambda))^T = \alpha^2 \delta_{kl} F^0(\lambda),
\end{equation}
\begin{equation}
((C^0(\lambda))^T)^* \cdot (C^0(\lambda))^T = \alpha^2 F^0(\lambda) B_1^T F^0(\lambda),
\end{equation}
\begin{equation}
((C^0(\lambda))^T)^* \cdot (C^0(\lambda))^T = F^0(\lambda) \tilde{\alpha} \cdot \tilde{\alpha}^* F^0(\lambda),
\end{equation}
constrained optimization problem (27) and restrictions on densities from the corresponding classes $D_0^k$, $k = 1, 2, 3, 4$. The minimax spectral characteristic of the optimal estimate of the functional $A^0_\xi$ is determined by the formula (18).
spectral densities for these sets of admissible spectral densities.

the admissible spectral density matrices are from the class $D$.

Consider the problem of minimax extrapolation of the functional $A\vec{\xi}$.

5. Least favorable spectral densities in the class $D = D_\varepsilon \times D_\delta$

Consider the problem of minimax extrapolation of the functional $A\vec{\xi}$ based on observations of the uncorrelated sequences in the case where the spectral density matrices of the observed sequences are not exactly known while the admissible spectral density matrices are from the class $D = D_\varepsilon \times D_\delta$, where

$$D^1_\varepsilon = \left\{ F(\lambda) \left| \text{Tr} \, F(\lambda) = (1 - \varepsilon) \text{Tr} \, F_1(\lambda) + \varepsilon \text{Tr} \, W(\lambda), \frac{1}{2\pi} \int_{-\pi}^{\pi} \text{Tr} \, F(\lambda) d\lambda = p \right. \right\};$$

$$D^1_\delta = \left\{ G(\lambda) \left| \frac{1}{2\pi} \int_{-\pi}^{\pi} |\text{Tr} \, (G(\lambda) - G_1(\lambda))| d\lambda \leq \delta \right. \right\};$$

$$D^2_\varepsilon = \left\{ F(\lambda) \left| f_{kk}(\lambda) = (1 - \varepsilon)f_{kk}^1(\lambda) + \varepsilon w_{kk}(\lambda), \frac{1}{2\pi} \int_{-\pi}^{\pi} f_{kk}(\lambda) d\lambda = p_k, k = 1, \ldots, T \right. \right\};$$

$$D^2_\delta = \left\{ G(\lambda) \left| \frac{1}{2\pi} \int_{-\pi}^{\pi} |g_{kk}(\lambda) - g_{kk}^1(\lambda)| d\lambda \leq \delta_k, k = 1, \ldots, T \right. \right\};$$

$$D^3_\varepsilon = \left\{ F(\lambda) \left| g_{kk}(\lambda) = (1 - \varepsilon)g_{kk}^1(\lambda) + \varepsilon g_{kk}(\lambda), \frac{1}{2\pi} \int_{-\pi}^{\pi} g_{kk}(\lambda) d\lambda = p_k, k = 1, \ldots, T \right. \right\};$$

$$D^3_\delta = \left\{ G(\lambda) \left| \frac{1}{2\pi} \int_{-\pi}^{\pi} |g_{kk}(\lambda) - g_{kk}^1(\lambda)| d\lambda \leq \delta_k, k = 1, \ldots, T \right. \right\};$$

Here $F_1(\lambda), G_1(\lambda)$ are known and fixed spectral densities, $W(\lambda)$ is an unknown spectral density, $p, \varepsilon, \delta, \delta_k, p_k, k = 1, \ldots, T$, are fixed numbers, $P$ is a fixed positive-definite Hermitian matrices.

From the condition $0 \in \partial D_\Delta (F^0, G^0)$ we find the following equations which determine the least favourable spectral densities for these sets of admissible spectral densities.

For the first pair $D^1_\varepsilon \times D^1_\delta$ we have equations

$$\left( r^0_G(\lambda) \right)^* \left( r^0_G(\lambda) \right) = (\alpha^2 + \gamma_1(\lambda))(F^0(\lambda) + G^0(\lambda))^2,$$

$$\left( r^0_F(\lambda) \right)^* \left( r^0_F(\lambda) \right) = \beta^2 \gamma_2(\lambda)(F^0(\lambda) + G^0(\lambda))^2,$$

$$\frac{1}{2\pi} \int_{-\pi}^{\pi} |\text{Tr} \, (G^0(\lambda) - G_1(\lambda))| d\lambda = \delta,$$

where $\alpha^2, \beta^2$ are Lagrange multipliers, $\gamma_1(\lambda) \leq 0$ and $\gamma_1(\lambda) = 0$ if $\text{Tr} \, F^0(\lambda) > (1 - \varepsilon)\text{Tr} \, F_1(\lambda), |\gamma_2(\lambda)| \leq 1$ and $\gamma_2(\lambda) = \text{sign} \, (\text{Tr} \, (G^0(\lambda) - G_1(\lambda)))$ if $\text{Tr} \, (G^0(\lambda) - G_1(\lambda)) \neq 0$.
For the second pair $D^2_ε × D^2_1$ we have equations

\[(r^0_G(λ))^*(r^0_G(λ))^T = (F^0(λ) + G^0(λ)) \left\{ (α^2 + γ^1_k(λ))δ_{kl} \right\}^T_{k,l=1} (F^0(λ) + G^0(λ)), \tag{49}\]

\[(r^0_P(λ))^*(r^0_P(λ))^T = (F^0(λ) + G^0(λ)) \left\{ β^2_k γ^2_k(λ)δ_{kl} \right\}^T_{k,l=1} (F^0(λ) + G^0(λ)), \tag{50}\]

\[
\frac{1}{2π} \int_{-π}^{π} |g^0_{kk}(λ) - g^1_{kk}(λ)| \, dλ = δ_k, \tag{51}\]

where $α^2, β^2_k$ are Lagrange multipliers, $γ^1_k(λ) ≤ 0$ and $γ^1_k(λ) = 0$ if $f^0_{kk}(λ) > (1 - ε)f^1_{kk}(λ)$, $|γ^2_k(λ)| ≤ 1$ and

\[
γ^2_k(λ) = \text{sign} (g^0_{kk}(λ) - g^1_{kk}(λ)) \text{ if } g^0_{kk}(λ) - g^1_{kk}(λ) ≠ 0, \, k = 1, T.
\]

For the third pair $D^3_ε × D^3_1$ we have equations

\[(r^0_G(λ))^*(r^0_G(λ))^T = (α^2 + γ^1_1(λ))(F^0(λ) + G^0(λ))B^1_1 (F^0(λ) + G^0(λ)), \tag{52}\]

\[(r^0_P(λ))^*(r^0_P(λ))^T = β^2 γ^2(λ)(F^0(λ) + G^0(λ))B^2_1 (F^0(λ) + G^0(λ)), \tag{53}\]

\[
\frac{1}{2π} \int_{-π}^{π} \left| ⟨B_2, G^0(λ) - G_1(λ)⟩ \right| \, dλ = δ, \tag{54}\]

where $α^2, β^2$ are Lagrange multipliers, $γ^1_1(λ) ≤ 0$ and $γ^1_1(λ) = 0$ if $⟨B_1, F^0(λ)⟩ > (1 - ε)⟨B_1, F_1(λ)⟩$, $|γ^2_2(λ)| ≤ 1$ and

\[
γ^2_2(λ) = \text{sign} ⟨B_2, G^0(λ) - G_1(λ)⟩ \text{ if } ⟨B_2, G^0(λ) - G_1(λ)⟩ ≠ 0.
\]

For the fourth pair $D^4_ε × D^4_1$ we have equations

\[(r^0_G(λ))^*(r^0_G(λ))^T = (F^0(λ) + G^0(λ))(α \cdot α^* + Γ(λ))(F^0(λ) + G^0(λ)), \tag{55}\]

\[(r^0_P(λ))^*(r^0_P(λ))^T = (F^0(λ) + G^0(λ)) (β_{ij} γ_{ij}(λ))^{T}_{i,j=1} (F^0(λ) + G^0(λ)), \tag{56}\]

\[
\frac{1}{2π} \int_{-π}^{π} |g^0_{ij}(λ) - g^1_{ij}(λ)| \, dλ = δ^I_{i,j}, \tag{57}\]

where $α, β_{ij}$ are Lagrange multipliers, $Γ(λ) ≤ 0$ and $Γ(λ) = 0$ if $F^0(λ) > (1 - ε)F_1(λ)$, $|γ_{ij}(λ)| ≤ 1$ and

\[
γ_{ij}(λ) = \frac{g^0_{ij}(λ) - g^1_{ij}(λ)}{g^0_{ij}(λ) - g^1_{ij}(λ)} \text{ if } g^0_{ij}(λ) - g^1_{ij}(λ) ≠ 0, \, i,j = 1, T.
\]

The following theorem and corollaries hold true.

**Theorem 5.1**

Let the minimality condition (12) hold true. The least favorable spectral densities $F^0(λ), G^0(λ)$ in the classes $D_ε × D_1$ for the optimal linear extrapolation of the functional $Aξ$ are determined by relations (46) – (48) for the first pair $D^1_ε × D^1_1$ of sets of admissible spectral densities; (49) – (51) for the second pair $D^2_ε × D^2_1$ of sets of admissible spectral densities; (52) – (54) for the third pair $D^3_ε × D^3_1$ of sets of admissible spectral densities; (55) – (57) for the fourth pair $D^4_ε × D^4_1$ of sets of admissible spectral densities; constrained optimization problem (26) and restrictions on densities from the corresponding classes $D_ε × D_1$. The minimax-robust spectral characteristic of the optimal estimate of the functional $Aξ$ is determined by the formula (13).

**Corollary 5.1**

Let the minimality condition (20) hold true. The least favorable spectral densities $F^0(λ)$ in the classes $D^k_ε$, $k = 1, 2, 3, 4$, for the optimal linear extrapolation of the functional $Aξ$ from observations of the sequence $ξ(j)$ at

points $j \in \mathbb{Z}_- \setminus S$, where $S = \bigcup_{l=1}^{8} \{-M_l - N_l, \ldots, -M_l\}$, are determined by the following equations, respectively,

$$((C^0(\lambda))^T \cdot (C^0(\lambda))^T = (\alpha^2 + \gamma(\lambda))(F^0(\lambda))^2, \quad (C^0(\lambda)) = F^0(\lambda) \{\alpha_k^2 + \gamma_k(\lambda)\delta_{kl}\}^T_{k,l=1} F^0(\lambda), \quad (C^0(\lambda))^T \cdot (C^0(\lambda))^T = (\alpha_k^2 + \gamma(\lambda))F^0(\lambda)B_1^T F^0(\lambda), \quad (C^0(\lambda))^T \cdot (C^0(\lambda))^T = F^0(\lambda)(\bar{\alpha} \cdot \bar{\alpha}^* + \Gamma(\lambda))F^0(\lambda),$$

constrained optimization problem (27) and restrictions on densities from the corresponding classes $D^k_{\lambda}$, $k = 1, 2, 3, 4$. The minimax spectral characteristic of the optimal estimate of the functional $\tilde{A}_\xi^0$ is determined by the formula (18).

**Corollary 5.2**

Let the minimality condition (20) hold true. The least favorable spectral densities $F^0(\lambda)$ in the classes $D^k_{\lambda}$, $k = 1, 2, 3, 4$, for the optimal linear extrapolation of the functional $A^0_\xi$ from observations of the sequence $\tilde{\xi}(j)$ at points $j \in \mathbb{Z}_- \setminus S$, where $S = \bigcup_{l=1}^{8} \{-M_l - N_l, \ldots, -M_l\}$, are determined by the following equations, respectively,

$$((C^0(\lambda))^T \cdot (C^0(\lambda))^T = \beta^2 \gamma_2(\lambda)(F^0(\lambda))^2, \quad (C^0(\lambda))^T \cdot (C^0(\lambda))^T = F^0(\lambda) \{\beta_k^2(\lambda)\delta_{kl}\}^T_{k,l=1} F^0(\lambda), \quad (C^0(\lambda))^T \cdot (C^0(\lambda))^T = \beta^2 \gamma_2(\lambda)F^0(\lambda)B_2^T F^0(\lambda), \quad (C^0(\lambda))^T \cdot (C^0(\lambda))^T = F^0(\lambda) \{\beta_{ij}(\lambda)\gamma_{ij}(\lambda)\}^T_{i,j=1} F^0(\lambda),$$

constrained optimization problem (27) and the following restrictions on densities from the corresponding classes $D^k_{\lambda}$, $k = 1, 2, 3, 4$, respectively,

$$\frac{1}{2\pi} \int_{-\pi}^{\pi} \left| \text{Tr} (F^0(\lambda) - G_1(\lambda)) \right| d\lambda = \delta, \quad \frac{1}{2\pi} \int_{-\pi}^{\pi} \left| J_{kk}(\lambda) - g^l_{kk}(\lambda) \right| d\lambda = \delta_k, \quad \frac{1}{2\pi} \int_{-\pi}^{\pi} \left| \langle B_2, F^0(\lambda) - G_1(\lambda) \rangle \right| d\lambda = \delta, \quad \frac{1}{2\pi} \int_{-\pi}^{\pi} \left| f_{ij}(\lambda) - g^l_{ij}(\lambda) \right| d\lambda = \delta^l_{i}.$$

The minimax spectral characteristic of the optimal estimate of the functional $A^0_\xi$ is determined by the formula (18).

6. Conclusions

In this article we describe methods of the mean-square optimal linear extrapolation of functionals which depend on the unknown values of a multidimensional stationary sequence. Estimates are based on observations of the sequence with an additive stationary noise sequence. We develop methods of finding the optimal estimates of the functionals in the case of missing observations. The problem is investigated in the case of spectral certainty, where the spectral densities of the sequences are exactly known. In this case we propose an approach based on the Hilbert space projection method. We derive formulas for calculating the spectral characteristics and the mean-square errors of the estimates of the functionals. In the case of spectral uncertainty, where the spectral densities of the sequences are

not exactly known while sets of admissible spectral densities are given, the minimax (robust) method of estimation is applied. This method allows us to find estimates that minimize the maximum values of the mean-square errors of estimates for all spectral density matrices from a given class of admissible spectral density matrices and derive relations which determine the least favourable spectral density matrices. These least favourable spectral density matrices are solutions of the optimization problem $\Delta_D(F, G) = - \Delta(h(F^0, G^0); F, G) + \delta((F, G) | D_F \times D_G) \rightarrow \inf$, which is characterized by the condition $0 \in \partial \Delta_D(F^0, G^0)$, where $\partial \Delta_D(F^0, G^0)$ is the subdifferential of the convex functional $\Delta_D(F, G)$ at point $(F^0, G^0)$. The form of the functional $\Delta(h(F^0, G^0); F, G)$ is convenient for application of the Lagrange method of indefinite multipliers for finding solution to the optimization problem. The complexity of the problem is determined by the complexity of calculation of the subdifferential of the convex functional $\Delta_D(F, G)$. Making use of the method of Lagrange multipliers and the form of subdifferentials of the indicator functions we describe relations that determine the least favourable spectral densities in some special classes of spectral densities. These are: classes $D_D$ of densities with the moment restrictions, classes $D_{D,\delta}$ which describe the “$\delta$-neighborhood” models in the space $L_1$ of a given bounded spectral density, classes $D_{UV}$ which describe the “strip” models of a given bounded spectral density, classes $D_{V\epsilon}$ which describe the “$\epsilon$-contamination” models of spectral densities.
